CYFER for SMEs: Escrow, Budget Tracking and Verified Payouts

Speaker script for the PaiFlow Hackathon deck

Team CYFER, CYFER for SMEs. One script block per slide. Total speaking time is about 7 to 8 minutes including the demo.

#	Slide	Time
1	Title	About 10 seconds
2	The hook	About 8 seconds
3	Problem	About 40 seconds
4	Solution and process	About 45 seconds
5	Impact	About 35 seconds
6	Paiflow integration	About 50 seconds
7	Live demonstration	About 3 to 4 minutes
8	Thank you	About 20 seconds

Note on the deck. Slides 9 to 13 in the file are leftover template slides from a different company (Arowwai Industries: AI workflow builder, market size, pricing, competitors, team). They have nothing to do with CYFER, so they have no script. Delete them before presenting.

Feature overview (say this in one breath if asked 'what does it do?')

Feature	What it does	Status
Hashed budget plan	Every plan is hashed, so a later change to the record can be detected.	Built
Unanimous approval	Every designated approver must approve. The server blocks payment until they do.	Built
One signed Split payment	The signer pays once in Freighter; Paiflow splits it Operations 50 / Payroll 30 / Supplies 20.	Built, not yet run on Testnet
Per-envelope payout verification	Each recipient's payout is checked separately. Dashboard: Planned, Approved, Pending, Verified distribution.	Built; envelope payouts may stay pending (event shape unconfirmed)
Budget vs actual	Approved share against verified amount per envelope, in stroops only.	Built (data and hook); screen pending
Money-movements log and CSV	A read-only expense log with spreadsheet export. Not a general ledger.	Built on our side; waits for a database function
Document tamper check	Upload a copy to see whether its bytes match the recorded hash.	Built by Francis; page /verify
Wallet page	Binding, balance and verified history. The app never holds keys.	Built (routes and hooks); page pending
Protected payment (escrow)	Funds held until a condition is met.	Should-have, not built

Feature	What it does	Status
Supplier registry, purchase-to-pay, approval thresholds	Directory of payees, PO-to-payment flow, rule-based approvals.	Future

Only present as done what is marked Built. Say Should-have and Future items as 'next', never as shipped.

Slide 1: Title

About 10 seconds
Slide: CYFER for SMEs. Team CYFER. 'Paiflow moves the money. CYFER proves what was approved and what was paid.'

We are Team CYFER, and this is CYFER for SMEs.

Paiflow moves the money. CYFER proves what was approved and what was paid.

Delivery note: Pause after the one-line pitch. Introduce each team member here.

Slide 2: The hook

About 8 seconds
Slide: 'Money moves. Accountability doesn't always follow.'

Money moves in seconds. Accountability does not always follow.

Can anyone prove it went where it should, and that the right people approved it?

Delivery note: Say this slowly and let the slide sit for a moment. No details yet.

Slide 3: Problem

About 40 seconds
Slide: 'Trust is not a paper trail.' Three problems: scattered records, unclear accountability, lack of payment proof. The gap.

Small and medium enterprises usually run on scattered tools. The budget is in a spreadsheet, the approval is in a chat, and the receipt is in an email.

That causes three problems. First, scattered records: budgets, approvals and receipts live on different platforms. Second, unclear accountability: owners struggle to verify who actually approved a financial decision. Third, a lack of payment proof: a transaction receipt shows that money moved, but it does not show that the money followed the approved budget.

That is the gap. Planning, approval and payment verification are usually separate workflows, so disputes are hard to settle.

Delivery note: Point to each of the three boxes as you name them.

Slide 4: Solution and process

About 45 seconds
Slide: 'CYFER: from approval to verified payment.' Plan, Approve, Pay, Verify.

CYFER connects those steps into one flow with four stages.

Plan: we create a budget plan and record its hash, so any later change to the plan can be detected.

Approve: every designated approver must approve. It is unanimous, and a payment cannot start without it. The server enforces this, not just the screen.

Pay: the authorised signer signs one payment in their own wallet, and Paiflow distributes the funds. CYFER never holds funds or keys.

Verify: we then check each recipient's payout against the approved plan. We only call a payment distributed after that check passes.

Delivery note: Key line: confirmed is not the same as verified. We show 'paid' only after the payout is verified.

Slide 5: Impact

About 35 seconds
Slide: 'Building financial trust for Filipino SMEs.' 99.63% of Philippine business establishments were MSMEs in 2023; 66.97% of employment in the reported establishment data. Potential impact list.

This matters because SMEs are the backbone of the Philippine economy. In 2023, 99.63 percent of business establishments were MSMEs, and they accounted for 66.97 percent of employment in the reported establishment data.

If these businesses can show who approved a payment and where the money went, we get better financial accountability, fewer disputes over approvals and payments, more transparency between business partners, and more accessible tools for responsible financial management.

Delivery note: Cite the source out loud if asked (the 2023 MSME figures on the slide). Do not claim more than the slide says.

Slide 6: Paiflow integration

About 50 seconds
Slide: 'Turning approved budgets into verifiable payments.' CYFER handles / Paiflow handles / example allocation 50-30-20.

Here is how the two systems divide the work.

CYFER handles the budget plan and document hashes, the unanimous approval records, and the audit trail and payout verification.

Paiflow handles Stellar-based payments, automated percentage-based fund splitting, and, as an additional feature, conditional payment protection.

In our example, one approved budget is split Operations 50 percent, Payroll 30 percent and Supplies 20 percent.

So: one approved payment, three configured destinations, and independently checked payout evidence for each.

Delivery note: Be clear that the split recipients are fixed for each deployment. A change means a new flow and a new approval. Conditional protection is an extra, not the core demo.

Slide 7: Live demonstration

About 3 to 4 minutes
Slide: 'Live demonstration.'

Now let us show it working.

Suggested order: (1) create the budget plan and show its hash; (2) show the approvals, and that payment is blocked until every approver has approved; (3) approve as the last approver; (4) the signer signs one payment in Freighter on Stellar Testnet; (5) show the dashboard move through Planned, Approved, Pending and Verified distribution, with each envelope verified separately; (6) upload a copy of the plan document to show the tamper check.

Delivery note: Say plainly that this is Stellar Testnet, a simulation, and that no real money moves. If a payout is still pending, say pending; do not call it paid. Have the recorded backup ready.

Slide 8: Thank you

About 20 seconds
Slide: 'CYFER: building trust through financial transparency.' Thank you. Presented by Team CYFER.

To sum up: Paiflow moves the money, and CYFER proves what was approved and what was paid.

Our aim is trust through financial transparency for small businesses. Thank you. We are happy to take your questions.

Delivery note: Stay on this slide for Q&A.;

Does the script match the application?

Matches the code: the one-line pitch, the Plan, Approve, Pay, Verify order, unanimous approval enforced on the server, a non-custodial Freighter-signed Split of 50/30/20, per-envelope verification, the honest wording (confirmed is not verified, Testnet is a simulation), and the tamper check.

Gap 1, no Testnet run yet: the Testnet rehearsal has not happened and the Paiflow token is not set. The live demo on slide 7 cannot show a real payment until it does. Until then, demo with fixture data (labelled FIXTURE) or the recorded backup, and say so.

Gap 2, envelope payouts may stay pending: the Split payout event shape is unconfirmed, so a live run may show the payment confirmed but each payout still pending. Say 'pending', never 'paid'.

Gap 3, screens: the repo has a plans list and a new-plan page, plus /verify and /transparency. There is no plan detail page or wallet page yet, so the demo steps for signing, the verified dashboard and the wallet depend on Shanti's screens.

Gap 4, slide 6 wording: 'Conditional payment protection' is correctly marked an additional feature. Do not demo it.

Gap 5, slide 5 claim: 'Greater transparency between business partners' is a goal, not something we have measured.

Likely questions and safe answers

Does CYFER hold the money?

No. Paiflow moves the funds. Users sign in their own wallet, and CYFER never holds funds or keys.

Does a verified payout prove the money was spent well?

No. It proves the distribution matched the approved plan, not that the spending was good.

Is the CYFER ledger on Stellar?

No. It is an application hash chain in our database. It is not public anchoring. Only the payment itself is on Stellar.

If a file does not match, was it tampered with?

Not necessarily. A mismatch means the bytes differ from what was recorded. It does not prove tampering.

Is this real money?

No. It runs on Stellar Testnet, which is a simulation.

What if a payment times out?

We check the original transaction. We never create a replacement payment when the outcome is uncertain.
